# Chapter 1. Introduction

XML-RPC is a format devised by Userland Software [<http://www.userland.com/>] for achieving remote procedure call via XML using HTTP as the transport. XML-RPC has its own web site, [www.xmlrpc.com](http://www.xmlrpc.com) [<http://www.xmlrpc.com/>]

This collection of PHP classes provides a framework for writing XML-RPC clients and servers in PHP.

Main goals of the project are ease of use, flexibility and completeness.

The original author is Edd Dumbill of Useful Information Company [<http://usefulinc.com/>]. As of the 1.0 stable release, the project has been opened to wider involvement and moved to SourceForge [<http://phpxmlrpc.sourceforge.net/>].

A list of XML-RPC implementations for other languages such as Perl and Python can be found on the [www.xmlrpc.com](http://www.xmlrpc.com) [<http://www.xmlrpc.com/>] site.

# Chapter 2. What's new

*Note:* not all items the following list have (yet) been fully documented, and some might not be present in any other chapter in the manual. To find a more detailed description of new functions and methods please take a look at the source code of the library, which is quite thoroughly commented in javadoc-like form.

## 2.2.2

*Note:* this might be the last release of the library that will support PHP 4. Future releases (if any) should target php 5.0 as minimum supported version.

- fixed: encoding of utf-8 characters outside of the BMP plane
- fixed: character set declarations surrounded by double quotes were not recognized in http headers
- fixed: be more tolerant in detection of charset in http headers
- fixed: fix detection of zlib.output\_compression
- fixed: use feof() to test if socket connections are to be closed instead of the number of bytes read (rare bug when communicating with some servers)
- fixed: format floating point values using the correct decimal separator even when php locale is set to one that uses comma
- fixed: improve robustness of the debugger when parsing weird results from non-compliant servers
- php warning when receiving 'false' in a bool value
- improved: allow the add\_to\_map server method to add docs for single params too
- improved: added the possibility to wrap for exposure as xmlrpc methods plain php class methods, object methods and even whole classes

## 2.2.1

- fixed: work around bug in php 5.2.2 which broke support of HTTP\_RAW\_POST\_DATA
- fixed: is\_dir parameter of setCaCertificate() method is reversed
- fixed: a php warning in xmlrpc\_client creator method
- fixed: parsing of '1e+1' as valid float
- fixed: allow errorlevel 3 to work when prev. error handler was a static method
- fixed: usage of client::setcookie() for multiple cookies in non-ssl mode
- improved: support for CP1252 charset is not part of the library but almost possible
- improved: more info when curl is enabled and debug mode is on

## 2.2

- fixed: debugger errors on php installs with magic\_quotes\_gpc on

- fixed: support for https connections via proxy
- fixed: `wrap_xmlrpc_method()` generated code failed to properly encode php objects
- improved: slightly faster encoding of data which is internally UTF-8
- improved: debugger always generates a 'null' id for jsonrpc if user omits it
- new: debugger can take advantage of a graphical value builder (it has to be downloaded separately, as part of jsxmlrpc package. See Appendix D for more details)
- new: support for the `<NIL/>` xmlrpc extension. see below for more details
- new: server support for the `system.getCapabilities` xmlrpc extension
- new: `wrap_xmlrpc_method()` [31] accepts two new options: `debug` and `return_on_fault`

## 2.1

- The `wrap_php_function` and `wrap_xmlrpc_method` functions have been moved out of the base library file `xmlrpc.inc` into a file of their own: `xmlrpc_wrappers.inc`. You will have to `include()` / `require()` it in your scripts if you have been using those functions. For increased security, the automatic rebuilding of php object instances out of received xmlrpc structs in `wrap_xmlrpc_method()` has been disabled (but it can be optionally re-enabled). Both `wrap_php_function()` and `wrap_xmlrpc_method()` functions accept many more options to fine tune their behaviour, including one to return the php code to be saved and later used as standalone php script
- The constructor of `xmlrpcval()` values has seen some internal changes, and it will not throw a php warning anymore when invoked using an unknown xmlrpc type: the error will only be written to php error log. Also new `xmlrpcval('true', 'boolean')` is not supported anymore
- The new function `php_xmlrpc_decode_xml()` will take the xml representation of either an xmlrpc request, response or single value and return the corresponding php-xmlrpc object instance
- A new function `wrap_xmlrpc_server()` has been added, to wrap all (or some) of the methods exposed by a remote xmlrpc server into a php class
- A new file has been added: `verify_compat.php`, to help users diagnose the level of compliance of their php installation with the library
- Restored compatibility with php 4.0.5 (for those poor souls still stuck on it)
- Method `xmlrpc_server->service()` now returns a value: either the response payload or `xmlrpcresp` object instance
- Method `xmlrpc_server->add_to_map()` now accepts xmlrpc methods with no param definitions
- Documentation for single parameters of exposed methods can be added to the dispatch map (and turned into html docs in conjunction with a future release of the 'extras' package)
- Full response payload is saved into `xmlrpcresp` object for further debugging
- The debugger can now generate code that wraps a remote method into a php function (works for jsonrpc, too); it also has better support for being activated via a single GET call (e.g. for integration into other tools)
- Stricter parsing of incoming xmlrpc messages: two more invalid cases are now detected (double data element inside array and struct/array after scalar inside value element)

- More logging of errors in a lot of situations
- Javadoc documentation of lib files (almost) complete
- Many performance tweaks and code cleanups, plus the usual crop of bugs fixed (see NEWS file for complete list of bugs)
- Lib internals have been modified to provide better support for grafting extra functionality on top of it. Stay tuned for future releases of the EXTRAS package (or go read Appendix B)...

## 2.0 final

- Added to the client class the possibility to use Digest and NTLM authentication methods (when using the CURL library) for connecting to servers and NTLM for connecting to proxies
- Added to the client class the possibility to specify alternate certificate files/directories for authenticating the peer with when using HTTPS communication
- Reviewed all examples and added a new demo file, containing a proxy to forward xmlrpc requests to other servers (useful e.g. for ajax coding)
- The debugger has been upgraded to reflect the new client capabilities
- All known bugs have been squashed, and the lib is more tolerant than ever of commonly-found mistakes

## 2.0 Release candidate 3

- Added to server class the property `functions_parameters_type`, that allows the server to register plain php functions as xmlrpc methods (i.e. functions that do not take an xmlrpcmsg object as unique param)
- let server and client objects serialize calls using a specified character set encoding for the produced xml instead of US-ASCII (ISO-8859-1 and UTF-8 supported)
- let `php_xmlrpc_decode` accept xmlrpcmsg objects as valid input
- 'class::method' syntax is now accepted in the server dispatch map
- `xmlrpc_client::SetDebug()` accepts integer values instead of a boolean value, with debugging level 2 adding to the information printed to screen the complete client request

## 2.0 Release candidate 2

- Added a new property of the client object: `xmlrpc_client->return_type`, indicating whether calls to the `send()` method will return `xmlrpcresp` objects whose `value()` is an `xmlrpcval` object, a php value (automatically decoded) or the raw xml received from the server.
- Added in the extras dir. two new library file: `jsonrpc.inc` and `jsonrpcs.inc` containing new classes that implement support for the json-rpc protocol (alpha quality code)
- Added a new client method: `setKey($key, $keypass)` to be used in HTTPS connections
- Added a new file containing some benchmarks in the testsuite directory

## 2.0 Release candidate 1

- Support for HTTP proxies (new method: `xmlrpc_client::setProxy()`)

- Support HTTP compression of both requests and responses. Clients can specify what kind of compression they accept for responses between deflate/gzip/any, and whether to compress the requests. Servers by default compress responses to clients that explicitly declare support for compression (new methods: `xmlrpc_client::setAcceptedCompression()`, `xmlrpc_client::setRequestCompression()`). Note that the ZLIB php extension needs to be enabled in PHP to support compression.
- Implement HTTP 1.1 connections, but only if CURL is enabled (added an extra parameter to `xmlrpc_client::xmlrpc_client` to set the desired HTTP protocol at creation time and a new supported value for the last parameter of `xmlrpc_client::send`, which now can be safely omitted if it has been specified at creation time)

With PHP versions greater than 4.3.8 keep-alives are enabled by default for HTTP 1.1 connections. This should yield faster execution times when making multiple calls in sequence to the same xmlrpc server from a single client.

- Introduce support for cookies. Cookies to be sent to the server with a request can be set using `xmlrpc_client::setCookie()`, while cookies received from the server are found in `xmlrpcresp::cookies()`. It is left to the user to check for validity of received cookies and decide whether they apply to successive calls or not.
- Better support for detecting different character set encodings of xml-rpc requests and responses: both client and server objects will correctly detect the charset encoding of received xml, and use an appropriate xml parser.

Supported encodings are US-ASCII, UTF-8 and ISO-8859-1.

- Added one new `xmlrpcmsg` constructor syntax, allowing usage of a single string with the complete URL of the target server
- Convert xml-rpc boolean values into native php values instead of 0 and 1
- Force the `php_xmlrpc_encode` function to properly encode numerically indexed php arrays into xml-rpc arrays (numerically indexed php arrays always start with a key of 0 and increment keys by values of 1)
- Prevent the `php_xmlrpc_encode` function from further re-encoding any objects of class `xmlrpcval` that are passed to it. This allows to call the function with arguments consisting of mixed php values / `xmlrpcval` objects.
- Allow a server to NOT respond to `system.*` method calls (setting the `$server->allow_system_funcs` property).
- Implement a new `xmlrpcval` method to determine if a value of type `struct` has a member of a given name without having to loop through all members: `xmlrpcval::structMemExists()`
- Expand methods `xmlrpcval::addArray`, `addScalar` and `addStruct` allowing extra php values to be added to `xmlrpcval` objects already formed.
- Let the `xmlrpc_client::send` method accept an XML string for sending instead of an `xmlrpcmsg` object, to facilitate debugging and integration with the php native xmlrpc extension
- Extend the `php_xmlrpc_encode` and `php_xmlrpc_decode` functions to allow serialization and rebuilding of PHP objects. To successfully rebuild a serialized object, the object class must be defined in the deserializing end of the transfer. Note that object members of type `resource` will be deserialized as `NULL` values.

Note that this has been implemented adding a "php\_class" attribute to xml representation of `xmlrpcval` of `STRUCT` type, which, strictly speaking, breaks the xml-rpc spec. Other xmlrpc implementations are supposed to ignore such an attribute (unless they implement a brain-dead custom xml parser...), so it should be safe enabling it in heterogeneous environments. The

activation of this feature is done by usage of an option passed as second parameter to both `php_xmlrpc_encode` and `php_xmlrpc_decode`.

- Extend the `php_xmlrpc_encode` function to allow automatic serialization of iso8601-conforming php strings as `datetime.iso8601` xmlrpcvals, by usage of an optional parameter
- Added an automatic stub code generator for converting xmlrpc methods to php functions and vice-versa.

This is done via two new functions: `wrap_php_function` and `wrap_xmlrpc_method`, and has many caveats, with php being a typeless language and all...

With PHP versions lesser than 5.0.3 wrapping of php functions into xmlrpc methods is not supported yet.

- Allow object methods to be used in server dispatch map
- Added a complete debugger solution, in the `debugger` folder
- Added configurable server-side debug messages, controlled by the new method `xmlrpc_server::SetDebug()`. At level 0, no debug messages are sent to the client; level 1 is the same as the old behaviour; at level 2 a lot more info is echoed back to the client, regarding the received call; at level 3 all warnings raised during server processing are trapped (this prevents breaking the xml to be echoed back to the client) and added to the debug info sent back to the client
- New XML parsing code, yields smaller memory footprint and faster execution times, not to mention complete elimination of the dreaded `eval()` construct, so prone to code injection exploits
- Rewritten most of the error messages, making text more explicative

---

## Chapter 3. System Requirements

The library has been designed with goals of scalability and backward compatibility. As such, it supports a wide range of PHP installs. Note that not all features of the lib are available in every configuration.

The *minimum supported* PHP version is 4.2.

A compatibility layer is provided that allows the code to run on PHP 4.0.5 and 4.1. Note that if you are stuck on those platforms, we suggest you upgrade as soon as possible.

Automatic generation of xml-rpc methods from php functions is only supported with PHP version 5.0.3 and later (note that the lib will generate some warnings with PHP 5 in strict error reporting mode).

If you wish to use SSL or HTTP 1.1 to communicate with remote servers, you need the "curl" extension compiled into your PHP installation. This is available in PHP 4.0.2 and greater, although 4.0.6 has a bug preventing SSL working, and versions prior to 4.3.8 do not support streamlining multiple requests using HTTP Keep-Alive.

The "xmlrpc" native extension is not required to be compiled into your PHP installation, but if it is, there will be no interference with the operation of this library.

---

# Chapter 4. Files in the distribution

lib/xmlrpc.inc	the XML-RPC classes. <code>include()</code> this in your PHP files to use the classes.
lib/xmlrpcs.inc	the XML-RPC server class. <code>include()</code> this in addition to <code>xmlrpc.inc</code> to get server functionality
lib/xmlrpc_wrappers.inc	helper functions to "automagically" convert plain php functions to xmlrpc services and vice versa
lib/compat/ array_key_exists.php, lib/ compat/is_a.php, lib/compat/ is_scalar.php, lib/compat/ var_export.php, lib/compat/ versions_compare.php	compatibility functions: these files implement the compatibility layer needed to run the library with PHP versions 4.0 and 4.1
demo/server/proxy.php	a sample server implementing xmlrpc proxy functionality.
demo/server/server.php	a sample server hosting various demo functions, as well as a full suite of functions used for interoperability testing. It is used by <code>testsuite.php</code> (see below) for unit testing the library, and is not to be copied literally into your production servers
demo/client/client.php, demo/ client/agesort.php, demo/client/ which.php	client code to exercise some of the functions in <code>server.php</code> , including the <code>interopechoTests.whichToolkit</code> method.
demo/client/wrap.php	client code to illustrate 'wrapping' of remote methods into php functions.
demo/client/introspect.php	client code to illustrate usage of introspection capabilities offered by <code>server.php</code> .
demo/client/mail.php	client code to illustrate usage of an xmlrpc-to-email gateway using Dave Winer's XML-RPC server at <a href="http://userland.com">userland.com</a> .
demo/client/zopetest.php	example client code that queries an xmlrpc server built in Zope.
demo/vardemo.php	examples of how to construct <code>xmlrpcval</code> types
demo/demo1.txt, demo/ demo2.txt, demo/demo3.txt	XML-RPC responses captured in a file for testing purposes (you can use these to test the <code>xmlrpcmsg-&gt;parseResponse()</code> method).
demo/server/discuss.php, demo/client/comment.php	Software used in the PHP chapter of The Jellyfish Book to provide a comment server and allow the attachment of comments to stories from Meerkat's data store.
test/testsuite.php, test/ parse_args.php	A unit test suite for this software package. If you do development on this software, please consider submitting tests for this suite.
test/benchmark.php	A (very limited) benchmarking suite for this software package. If you do development on this software, please consider submitting benchmarks for this suite.
test/phpunit.php, test/PHPUnit/ *.php	An (incomplete) version PEAR's unit test framework for PHP. The complete package can be found at <a href="http://pear.php.net/package/PHPUnit">http://pear.php.net/package/PHPUnit</a>

test/verify_compat.php	Script designed to help the user to verify the level of compatibility of the library with the current php install
extras/test.pl, extras/test.py	Perl and Python programs to exercise server.php to test that some of the methods work.
extras/ workspace.testPhpServer.fttb	Frontier scripts to exercise the demo server. Thanks to Dave Winer for permission to include these. See Dave's announcement of these. [ <a href="http://www.xmlrpc.com/discuss/msgReader\$853">http://www.xmlrpc.com/discuss/msgReader\$853</a> ]
extras/rsakey.pem	A test certificate key for the SSL support, which can be used to generate dummy certificates. It has the passphrase "test."

---

# Chapter 5. Known bugs and limitations

This started out as a bare framework. Many "nice" bits haven't been put in yet. Specifically, very little type validation or coercion has been put in. PHP being a loosely-typed language, this is going to have to be done explicitly (in other words: you can call a lot of library functions passing them arguments of the wrong type and receive an error message only much further down the code, where it will be difficult to understand).

`dateTime.iso8601` is supported opaquely. It can't be done natively as the XML-RPC specification explicitly forbids passing of timezone specifiers in ISO8601 format dates. You can, however, use the `iso8601_encode()` and `iso8601_decode()` functions to do the encoding and decoding for you.

Very little HTTP response checking is performed (e.g. HTTP redirects are not followed and the Content-Length HTTP header, mandated by the xml-rpc spec, is not validated); cookie support still involves quite a bit of coding on the part of the user.

If a specific character set encoding other than US-ASCII, ISO-8859-1 or UTF-8 is received in the HTTP header or XML prologue of xml-rpc request or response messages then it will be ignored for the moment, and the content will be parsed as if it had been encoded using the charset defined by `xmlrpc_defencoding`

Very large floating point numbers are serialized using exponential notation, even though the spec explicitly forbids this behaviour. This will not be a problem if this library is used on both ends of the communication, but might cause problems with other implementations.

Support for receiving from servers version 1 cookies (i.e. conforming to RFC 2965) is quite incomplete, and might cause unforeseen errors.

A PHP warning will be generated in many places when using `xmlrpc.inc` and `xmlrpcs.inc` with PHP 5 in strict error reporting mode. The simplest workaround to this problem is to lower the `error_reporting` level in `php.ini`.

---

# Chapter 6. Support

## Online Support

XML-RPC for PHP is offered "as-is" without any warranty or commitment to support. However, informal advice and help is available via the XML-RPC for PHP website and mailing list and from XML-RPC.com.

- The *XML-RPC for PHP* development is hosted on [phpxmlrpc.sourceforge.net](http://phpxmlrpc.sourceforge.net) [<http://phpxmlrpc.sourceforge.net>]. Bugs, feature requests and patches can be posted to the project's website [<http://sourceforge.net/projects/phpxmlrpc>].
- The *PHP XML-RPC interest mailing list* is run by the author. More details can be found here [<http://lists.gnomehack.com/mailman/listinfo/phpxmlrpc>].
- For more general XML-RPC questions, there is a Yahoo! Groups XML-RPC mailing list [<http://groups.yahoo.com/group/xml-rpc/>].
- The XML-RPC.com [<http://www.xmlrpc.com/discuss>] discussion group is a useful place to get help with using XML-RPC. This group is also gatewayed into the Yahoo! Groups mailing list.

## The Jellyfish Book

Together with Simon St.Laurent and Joe Johnston, Edd Dumbill wrote a book on XML-RPC for O'Reilly and Associates on XML-RPC. It features a rather fetching jellyfish on the cover.

Complete details of the book are available from O'Reilly's web site. [<http://www.oreilly.com/catalog/progxmlrpc/>]

Edd is responsible for the chapter on PHP, which includes a worked example of creating a forum server, and hooking it up the O'Reilly's Meerkat [<http://meerkat.oreillynet.com/>] service in order to allow commenting on news stories from around the Web.

If you've benefited from the effort that has been put into writing this software, then please consider buying the book!

---

# Chapter 7. Class documentation

## xmlrpcval

This is where a lot of the hard work gets done. This class enables the creation and encapsulation of values for XML-RPC.

Ensure you've read the XML-RPC spec at [http://www.xmlrpc.com/stories/storyReader\\$7](http://www.xmlrpc.com/stories/storyReader$7) before reading on as it will make things clearer.

The `xmlrpcval` class can store arbitrarily complicated values using the following types: `i4` `int` `boolean` `string` `double` `dateTime.iso8601` `base64` `array` `struct`. You should refer to the spec [<http://www.xmlrpc.com/spec>] for more information on what each of these types mean.

## Notes on types

### int

The type `i4` is accepted as a synonym for `int` when creating `xmlrpcval` objects. The xml parsing code will always convert `i4` to `int`: `int` is regarded by this implementation as the canonical name for this type.

### base64

Base 64 encoding is performed transparently to the caller when using this type. Decoding is also transparent. Therefore you ought to consider it as a "binary" data type, for use when you want to pass data that is not 7-bit clean.

### boolean

The php values `true` and `1` map to `true`. All other values (including the empty string) are converted to `false`.

### string

Characters `<`, `>`, `'`, `"`, `&`, are encoded using their entity reference as `&lt;`, `&gt;`, `&apos;`, `&quot;`, and `&amp;`. All other characters outside of the ASCII range are encoded using their character reference representation (e.g. `&#200` for `é`). The XML-RPC spec recommends only encoding `<` & but this implementation goes further, for reasons explained by the XML 1.0 recommendation [<http://www.w3.org/TR/REC-xml#syntax>]. In particular, using character reference representation has the advantage of producing XML that is valid independently of the charset encoding assumed.

## Creation

The constructor is the normal way to create an `xmlrpcval`. The constructor can take these forms:

```
xmlrpcval new xmlrpcval ( void )

xmlrpcval new xmlrpcval ( string $stringValue )

xmlrpcval new xmlrpcval ( mixed $scalarVal, string $scalartyp )

xmlrpcval new xmlrpcval ( array $arrayVal, string $arraytyp )
```

The first constructor creates an empty value, which must be altered using the methods `addScalar`, `addArray` or `addStruct` before it can be used.

The second constructor creates a simple string value.

The third constructor is used to create a scalar value. The second parameter must be a name of an XML-RPC type. Valid types are: "int", "boolean", "string", "double", "dateTime.iso8601", "base64".

Examples:

```
$myInt = new xmlrpcvalue(1267, "int");
$myString = new xmlrpcvalue("Hello, World!", "string");
$myBool = new xmlrpcvalue(1, "boolean");
$myString2 = new xmlrpcvalue(1.24, "string"); // note: this will serialize a php float value as xml
```

The fourth constructor form can be used to compose complex XML-RPC values. The first argument is either a simple array in the case of an XML-RPC array or an associative array in the case of a struct. The elements of the array *must be xmlrpcval objects themselves*.

The second parameter must be either "array" or "struct".

Examples:

```
$myArray = new xmlrpcval(
    array(
        new xmlrpcval("Tom"),
        new xmlrpcval("Dick"),
        new xmlrpcval("Harry")
    ),
    "array");

// recursive struct
$myStruct = new xmlrpcval(
    array(
        "name" => new xmlrpcval("Tom", "string"),
        "age" => new xmlrpcval(34, "int"),
        "address" => new xmlrpcval(
            array(
                "street" => new xmlrpcval("Fifht Ave", "string"),
                "city" => new xmlrpcval("NY", "string")
            ),
            "struct"
        )
    ),
    "struct");
```

See the file `vardemo.php` in this distribution for more examples.

## Methods

### addScalar

```
int addScalar ( string $stringVal )
```

```
int addScalar ( mixed $scalarVal, string $scalartyp )
```

If `$val` is an empty `xmlrpcval` this method makes it a scalar value, and sets that value.

If `$val` is already a scalar value, then no more scalars can be added and 0 is returned.

If `$val` is an `xmlrpcval` of type array, the php value `$scalarval` is added as its last element.

If all went OK, 1 is returned, otherwise 0.

### addArray

```
int addArray ( array $arrayVal )
```

The argument is a simple (numerically indexed) array. The elements of the array *must be xmlrpcval objects themselves*.

Turns an empty xmlrpcval into an array with contents as specified by *\$arrayVal*.

If *\$val* is an xmlrpcval of type array, the elements of *\$arrayVal* are appended to the existing ones.

See the fourth constructor form for more information.

If all went OK, 1 is returned, otherwise 0.

## addStruct

```
int addStruct ( array $assocArrayVal )
```

The argument is an associative array. The elements of the array *must be xmlrpcval objects themselves*.

Turns an empty xmlrpcval into a struct with contents as specified by *\$assocArrayVal*.

If *\$val* is an xmlrpcval of type struct, the elements of *\$arrayVal* are merged with the existing ones.

See the fourth constructor form for more information.

If all went OK, 1 is returned, otherwise 0.

## kindOf

```
string kindOf ( void )
```

Returns a string containing "struct", "array" or "scalar" describing the base type of the value. If it returns "undef" it means that the value hasn't been initialised.

## serialize

```
string serialize ( void )
```

Returns a string containing the XML-RPC representation of this value.

## scalarVal

```
mixed scalarVal ( void )
```

If *\$val->kindOf()* == "scalar", this method returns the actual PHP-language value of the scalar (base 64 decoding is automatically handled here).

## scalarTyp

```
string scalarTyp ( void )
```

If *\$val->kindOf()* == "scalar", this method returns a string denoting the type of the scalar. As mentioned before, *i4* is always coerced to *int*.

## arrayMem

```
xmlrpcval arrayMem ( int $n )
```

If *\$val->kindOf()* == "array", returns the *\$nth* element in the array represented by the value *\$val*. The value returned is an xmlrpcval object.

```
// iterating over values of an array object
for ($i = 0; $i < $val->arraySize(); $i++)
{
    $v = $val->arrayMem($i);
    echo "Element $i of the array is of type ".$v->kindOf();
}
```

## arraySize

```
int arraySize ( void )
```

If *\$val* is an array, returns the number of elements in that array.

## structMem

```
xmlrpcval structMem ( string $memberName )
```

If *\$val->kindOf()* == "struct", returns the element called *\$memberName* from the struct represented by the value *\$val*. The value returned is an xmlrpcval object.

## structEach

```
array structEach ( void )
```

Returns the next (key, value) pair from the struct, when *\$val* is a struct. *\$value* is an xmlrpcval itself. See also structreset().

```
// iterating over all values of a struct object
$val->structreset();
while (list($key, $v) = $val->structEach())
{
    echo "Element $key of the struct is of type ".$v->kindOf();
}
```

## structReset

```
void structReset ( void )
```

Resets the internal pointer for structEach() to the beginning of the struct, where *\$val* is a struct.

## structMemExists

```
bool structMemExists ( string $memberName )
```

Returns TRUE or FALSE depending on whether a member of the given name exists in the struct.

# xmlrpcmsg

This class provides a representation for a request to an XML-RPC server. A client sends an xmlrpcmsg to a server, and receives back an xmlrpcresp (see xmlrpc\_client->send).

## Creation

The constructor takes the following forms:

```
xmlrpcmsg new xmlrpcmsg ( string $methodName, array $parameterArray
= null )
```

Where *methodName* is a string indicating the name of the method you wish to invoke, and *parameterArray* is a simple php Array of `xmlrpcval` objects. Here's an example message to the *US state name* server:

```
$msg = new xmlrpcmsg("examples.getStateName", array(new xmlrpcval(23, "int")));
```

This example requests the name of state number 23. For more information on `xmlrpcval` objects, see `xmlrpcval`.

Note that the *parameterArray* parameter is optional and can be omitted for methods that take no input parameters or if you plan to add parameters one by one.

## Methods

### addParam

```
bool addParam ( xmlrpcval $xmlrpcVal )
```

Adds the `xmlrpcval` *xmlrpcVal* to the parameter list for this method call. Returns TRUE or FALSE on error.

### getNumParams

```
int getNumParams ( void )
```

Returns the number of parameters attached to this message.

### getParam

```
xmlrpcval getParam ( int $n )
```

Gets the *n*th parameter in the message (with the index zero-based). Use this method in server implementations to retrieve the values sent by the client.

### method

```
string method ( void )
```

```
string method ( string $methName )
```

Gets or sets the method contained in the XML-RPC message.

### parseResponse

```
xmlrpcresp parseResponse ( string $xmlString )
```

Given an incoming XML-RPC server response contained in the string *\$xmlString*, this method constructs an `xmlrpcresp` response object and returns it, setting error codes as appropriate (see `xmlrpc_client->send`).

This method processes any HTTP/MIME headers it finds.

### parseResponseFile

```
xmlrpcresp parseResponseFile ( file handle resource $fileHandle )
```

Given an incoming XML-RPC server response on the open file handle *fileHandle*, this method reads all the data it finds and passes it to `parseResponse`.

This method is useful to construct responses from pre-prepared files (see files `demo1.txt`, `demo2.txt`, `demo3.txt` in this distribution). It processes any HTTP headers it finds, and does not close the file handle.

## serialize

```
string serialize ( void )
```

Returns the an XML string representing the XML-RPC message.

# xmlrpc\_client

This is the basic class used to represent a client of an XML-RPC server.

## Creation

The constructor accepts one of two possible syntaxes:

```
xmlrpc_client new xmlrpc_client ( string $server_url )
```

```
xmlrpc_client new xmlrpc_client ( string $server_path, string  
$server_hostname, int $server_port = 80, string $transport = 'http' )
```

Here are a couple of usage examples of the first form:

```
$client = new xmlrpc_client("http://phpxmlrpc.sourceforge.net/server.php");  
$another_client = new xmlrpc_client("https://james:bond@secret.service.com:4443/xmlrpcserver?agent="
```

The second syntax does not allow to express a username and password to be used for basic HTTP authorization as in the second example above, but instead it allows to choose whether xmlrpc calls will be made using the HTTP 1.0 or 1.1 protocol.

Here's another example client set up to query Userland's XML-RPC server at *betty.userland.com*:

```
$client = new xmlrpc_client("/RPC2", "betty.userland.com", 80);
```

The *server\_port* parameter is optional, and if omitted will default to 80 when using HTTP and 443 when using HTTPS (see the `xmlrpc_client->send` method below).

The *transport* parameter is optional, and if omitted will default to 'http'. Allowed values are either 'http', 'https' or 'http11'. Its value can be overridden with every call to the `send` method. See the `send` method below for more details about the meaning of the different values.

## Methods

This class supports the following methods.

### send

This method takes the forms:

```
xmlrpcresp send ( xmlrpcmsg $xmlrpc_message, int $timeout, string  
$transport )
```

```
array send ( array $xmlrpc_messages, int $timeout, string $transport )
```

```
xmlrpcresp send ( string $xml_payload, int $timeout, string  
$transport )
```

Where *xmlrpc\_message* is an instance of *xmlrpcmsg* (see *xmlrpcmsg*), and *response* is an instance of *xmlrpcresp* (see *xmlrpcresp*).

If *xmlrpc\_messages* is an array of message instances, *responses* will be an array of response instances. The client will try to make use of a single `system.multicall` xml-rpc method call to forward to the server all the messages in a single HTTP round trip, unless `$client->no_multicall` has been previously set to `TRUE` (see the `multicall` method below), in which case many consecutive xmlrpc requests will be sent.

The third syntax allows to build by hand (or any other means) a complete xmlrpc request message, and send it to the server. *xml\_payload* should be a string containing the complete xml representation of the request. It is e.g. useful when, for maximal speed of execution, the request is serialized into a string using the native php xmlrpc functions (see the php manual on xmlrpc [<http://www.php.net/xmlrpc>]).

The *timeout* is optional, and will be set to 0 (wait for platform-specific predefined timeout) if omitted. This timeout value is passed to `fsockopen()`. It is also used for detecting server timeouts during communication (i.e. if the server does not send anything to the client for *timeout* seconds, the connection will be closed).

The *transport* parameter is optional, and if omitted will default to the transport set using instance creator or 'http' if omitted. The only other valid values are 'https', which will use an SSL HTTP connection to connect to the remote server, and 'http11'. Note that your PHP must have the "curl" extension compiled in order to use both these features. Note that when using SSL you should normally set your port number to 443, unless the SSL server you are contacting runs at any other port.

## Warning

PHP 4.0.6 has a bug which prevents SSL working.

In addition to low-level errors, the XML-RPC server you were querying may return an error in the *xmlrpcresp* object. See *xmlrpcresp* for details of how to handle these errors.

## multiCall

This method takes the form:

```
array multiCall ( array $messages, int $timeout, string $transport,
bool $fallback )
```

This method is used to boxcar many method calls in a single xml-rpc request. It will try first to make use of the `system.multicall` xml-rpc method call, and fall back to executing many separate requests if the server returns any error.

*msgs* is an array of *xmlrpcmsg* objects (see *xmlrpcmsg*), and *response* is an array of *xmlrpcresp* objects (see *xmlrpcresp*).

The *timeout* and *transport* parameters are optional, and behave as in the `send` method above.

The *fallback* parameter is optional, and defaults to `TRUE`. When set to `FALSE` it will prevent the client to try using many single method calls in case of failure of the first multicall request. It should be set only when the server is known to support the multicall extension.

## setAcceptedCompression

```
void setAcceptedCompression ( string $compressionmethod )
```

This method defines whether the client will accept compressed xml payload forming the bodies of the xmlrpc responses received from servers. Note that enabling reception of compressed responses merely adds some standard http headers to xmlrpc requests. It is up to the xmlrpc server to return compressed responses when receiving such requests. Allowed values for *compressionmethod* are: 'gzip', 'deflate', 'any' or null (with any meaning either gzip or deflate).

This requires the "zlib" extension to be enabled in your php install. If it is, by default `xmlrpc_client` instances will enable reception of compressed content.

## setCaCertificate

```
void setCaCertificate ( string $certificate, bool $is_dir )
```

This method sets an optional certificate to be used in SSL-enabled communication to validate a remote server with (when the `server_method` is set to 'https' in the client's construction or in the send method and `SetSSLVerifyPeer` has been set to TRUE).

The `certificate` parameter must be the filename of a PEM formatted certificate, or a directory containing multiple certificate files. The `is_dir` parameter defaults to FALSE, set it to TRUE to specify that `certificate` indicates a directory instead of a single file.

This requires the "curl" extension to be compiled into your installation of PHP. For more details see the man page for the `curl_setopt` function.

## setCertificate

```
void setCertificate ( string $certificate, string $passphrase )
```

This method sets the optional certificate and passphrase used in SSL-enabled communication with a remote server (when the `server_method` is set to 'https' in the client's construction or in the send method).

The `certificate` parameter must be the filename of a PEM formatted certificate. The `passphrase` parameter must contain the password required to use the certificate.

This requires the "curl" extension to be compiled into your installation of PHP. For more details see the man page for the `curl_setopt` function.

Note: to retrieve information about the client certificate on the server side, you will need to look into the environment variables which are set up by the webserver. Different webserver will typically set up different variables.

## setCookie

```
void setCookie ( string $name, string $value, string $path, string $domain, int $port )
```

This method sets a cookie that will be sent to the xmlrpc server along with every further request (useful e.g. for keeping session info outside of the xml-rpc payload).

`$value` is optional, and defaults to null.

`$path`, `$domain` and `$port` are optional, and will be omitted from the cookie header if unspecified. Note that setting any of these values will turn the cookie into a 'version 1' cookie, that might not be fully supported by the server (see RFC2965 for more details).

## setCredentials

```
void setCredentials ( string $username, string $password, int $authtype )
```

This method sets the username and password for authorizing the client to a server. With the default (HTTP) transport, this information is used for HTTP Basic authorization. Note that username and password can also be set using the class constructor. With HTTP 1.1 and HTTPS transport, NTLM and Digest authentication protocols are also supported. To enable them use the constants `CURLAUTH_DIGEST` and `CURLAUTH_NTLM` as values for the `authtype` parameter.

## setDebug

```
void setDebug ( int $debugLvl )
```

*debugLvl* is either 0, 1 or 2 depending on whether you require the client to print debugging information to the browser. The default is not to output this information (0).

The debugging information at level 1 includes the raw data returned from the XML-RPC server it was querying (including both HTTP headers and the full XML payload), and the PHP value the client attempts to create to represent the value returned by the server. At level 2, the complete payload of the xmlrpc request is also printed, before being sent to the server.

This option can be very useful when debugging servers as it allows you to see exactly what the client sends and the server returns.

## setKey

```
void setKey ( int $key, int $keypass )
```

This method sets the optional certificate key and passphrase used in SSL-enabled communication with a remote server (when the *transport* is set to 'https' in the client's construction or in the send method).

This requires the "curl" extension to be compiled into your installation of PHP. For more details see the man page for the `curl_setopt` function.

## setProxy

```
void setProxy ( string $proxyhost, int $proxyport, string $proxyusername, string $proxypassword, int $authtype )
```

This method enables calling servers via an HTTP proxy. The *proxyusername*, *proxypassword* and *authtype* parameters are optional. *Authtype* defaults to `CURLAUTH_BASIC` (Basic authentication protocol); the only other valid value is the constant `CURLAUTH_NTLM`, and has effect only when the client uses the HTTP 1.1 protocol.

NB: CURL versions before 7.11.10 cannot use a proxy to communicate with https servers.

## setRequestCompression

```
void setRequestCompression ( string $compressionmethod )
```

This method defines whether the xml payload forming the request body will be sent to the server in compressed format, as per the HTTP specification. This is particularly useful for large request parameters and over slow network connections. Allowed values for *compressionmethod* are: 'gzip', 'deflate', 'any' or null (with any meaning either gzip or deflate). Note that there is no automatic fallback mechanism in place for errors due to servers not supporting receiving compressed request bodies, so make sure that the particular server you are querying does accept compressed requests before turning it on.

This requires the "zlib" extension to be enabled in your php install.

## setSSLVerifyHost

```
void setSSLVerifyHost ( int $i )
```

This method defines whether connections made to XML-RPC backends via HTTPS should verify the remote host's SSL certificate's common name (CN). By default, only the existence of a CN is checked. *\$i* should be an integer value; 0 to not check the CN at all, 1 to merely check for its existence, and 2 to check that the CN on the certificate matches the hostname that is being connected to.

## setSSLVerifyPeer

```
void setSSLVerifyPeer ( bool $i )
```

This method defines whether connections made to XML-RPC backends via HTTPS should verify the remote host's SSL certificate, and cause the connection to fail if the cert verification fails. *\$i* should be a boolean value. Default value: TRUE. To specify custom SSL certificates to validate the server with, use the `setCaCertificate` method.

## Variables

NB: direct manipulation of these variables is only recommended for advanced users.

### no\_multicall

This member variable determines whether the `multicall()` method will try to take advantage of the `system.multicall xmlrpc` method to dispatch to the server an array of requests in a single http roundtrip or simply execute many consecutive http calls. Defaults to FALSE, but it will be enabled automatically on the first failure of execution of `system.multicall`.

### request\_charset\_encoding

This is the charset encoding that will be used for serializing request sent by the client.

If defaults to NULL, which means using US-ASCII and encoding all characters outside of the ASCII range using their xml character entity representation (this has the benefit that line end characters will not be mangled in the transfer, a CR-LF will be preserved as well as a single LF).

Valid values are 'US-ASCII', 'UTF-8' and 'ISO-8859-1'

### return\_type

This member variable determines whether the value returned inside an `xmlrpcresp` object as results of calls to the `send()` and `multicall()` methods will be an `xmlrpcval` object, a plain php value or a raw xml string. Allowed values are 'xmlrpcvals' (the default), 'phpvals' and 'xml'. To allow the user to differentiate between a correct and a faulty response, fault responses will be returned as `xmlrpcresp` objects in any case. Note that the 'phpvals' setting will yield faster execution times, but some of the information from the original response will be lost. It will be e.g. impossible to tell whether a particular php string value was sent by the server as an xmlrpc string or base64 value.

Example usage:

```
$client = new xmlrpc_client("phpxmlrpc.sourceforge.net/server");
$client->return_type = 'phpvals';
$message = new xmlrpcmsg("examples.getStateName", array(new xmlrpcval(23, "int")));
$resp = $client->send($message);
if ($resp->faultCode()) echo 'KO. Error: ' . $resp->faultString(); else echo 'OK: got ' . $resp->value()
```

For more details about usage of the 'xml' value, see Appendix A.

## xmlrpcresp

This class is used to contain responses to XML-RPC requests. A server method handler will construct an `xmlrpcresp` and pass it as a return value. This same value will be returned by the result of an invocation of the `send` method of the `xmlrpc_client` class.

## Creation

```
xmlrpcresp new xmlrpcresp ( xmlrpcval $xmlrpcval )
```

```
xmlrpcresp new xmlrpcresp ( 0, int $errcode, string $err_string )
```

The first syntax is used when execution has happened without difficulty: *\$xmlrpcval* is an *xmlrpcval* value with the result of the method execution contained in it. Alternatively it can be a string containing the xml serialization of the single xml-rpc value result of method execution.

The second type of constructor is used in case of failure. *errcode* and *err\_string* are used to provide indication of what has gone wrong. See *xmlrpc\_server* for more information on passing error codes.

## Methods

### faultCode

```
int faultCode ( void )
```

Returns the integer fault code return from the XML-RPC response. A zero value indicates success, any other value indicates a failure response.

### faultString

```
string faultString ( void )
```

Returns the human readable explanation of the fault indicated by *\$resp->faultCode()*.

### value

```
xmlrpcval value ( void )
```

Returns an *xmlrpcval* object containing the return value sent by the server. If the response's *faultCode* is non-zero then the value returned by this method should not be used (it may not even be an object).

Note: if the *xmlrpcresp* instance in question has been created by an *xmlrpc\_client* object whose *return\_type* was set to 'phpvals', then a plain php value will be returned instead of an *xmlrpcval* object. If the *return\_type* was set to 'xml', an xml string will be returned (see the *return\_type* member var above for more details).

### serialize

```
string serialize ( void )
```

Returns an XML string representation of the response (xml prologue not included).

## xmlrpc\_server

The implementation of this class has been kept as simple to use as possible. The constructor for the server basically does all the work. Here's a minimal example:

```
function foo ($xmlrpcmsg) {  
    ...  
    return new xmlrpcresp($some_xmlrpc_val);  
}  
  
class bar {  
    function foobar($xmlrpcmsg) {  
        ...  
        return new xmlrpcresp($some_xmlrpc_val);  
    }  
}
```

```
}

$s = new xmlrpc_server(
    array(
        "examples.myFunc1" => array("function" => "foo"),
        "examples.myFunc2" => array("function" => "bar::foobar"),
    ));
```

This performs everything you need to do with a server. The single constructor argument is an associative array from xmlrpc method names to php function names. The incoming request is parsed and dispatched to the relevant php function, which is responsible for returning a `xmlrpcresp` object, that will be serialized back to the caller.

## Method handler functions

Both php functions and class methods can be registered as xmlrpc method handlers.

The synopsis of a method handler function is:

```
xmlrpcresp $resp = function (xmlrpcmsg $msg)
```

No text should be echoed 'to screen' by the handler function, or it will break the xml response sent back to the client. This applies also to error and warning messages that PHP prints to screen unless the appropriate parameters have been set in the `php.ini` file. Another way to prevent echoing of errors inside the response and facilitate debugging is to use the server `SetDebug` method with debug level 3 (see below).

Note that if you implement a method with a name prefixed by `system.` the handler function will be invoked by the server with two parameters, the first being the server itself and the second being the `xmlrpcmsg` object.

The same php function can be registered as handler of multiple xmlrpc methods.

Here is a more detailed example of what the handler function `foo` may do:

```
function foo ($xmlrpcmsg) {
    global $xmlrpcerruser; // import user errcode base value

    $meth = $xmlrpcmsg->method(); // retrieve method name
    $par = $xmlrpcmsg->getParam(0); // retrieve value of first parameter - assumes at least one par
    $val = $par->scalarval(); // decode value of first parameter - assumes it is a scalar value

    ...

    if ($err) {
        // this is an error condition
        return new xmlrpcresp(0, $xmlrpcerruser+1, // user error 1
            "There's a problem, Captain");
    } else {
        // this is a successful value being returned
        return new xmlrpcresp(new xmlrpcval("All's fine!", "string"));
    }
}
```

See `server.php` in this distribution for more examples of how to do this.

Since release 2.0RC3 there is a new, even simpler way of registering php functions with the server. See section 5.7 below

## The dispatch map

The first argument to the `xmlrpc_server` constructor is an array, called the *dispatch map*. In this array is the information the server needs to service the XML-RPC methods you define.

The dispatch map takes the form of an associative array of associative arrays: the outer array has one entry for each method, the key being the method name. The corresponding value is another associative array, which can have the following members:

- `function` - this entry is mandatory. It must be either a name of a function in the global scope which services the XML-RPC method, or an array containing an instance of an object and a static method name (for static class methods the `'class::method'` syntax is also supported).
- `signature` - this entry is an array containing the possible signatures (see Signatures) for the method. If this entry is present then the server will check that the correct number and type of parameters have been sent for this method before dispatching it.
- `docstring` - this entry is a string containing documentation for the method. The documentation may contain HTML markup.
- `signature_docs` - this entry can be used to provide documentation for the single parameters. It must match in structure the `'signature'` member. By default, only the `documenting_xmlrpc_server` class in the `extras` package will take advantage of this, since the `"system.methodHelp"` protocol does not support documenting method parameters individually.

Look at the `server.php` example in the distribution to see what a dispatch map looks like.

## Method signatures

A signature is a description of a method's return type and its parameter types. A method may have more than one signature.

Within a server's dispatch map, each method has an array of possible signatures. Each signature is an array of types. The first entry is the return type. For instance, the method

```
string examples.getStateName(int)
```

has the signature

```
array($xmlrpcString, $xmlrpcInt)
```

and, assuming that it is the only possible signature for the method, it might be used like this in server creation:

```
$findstate_sig = array(array($xmlrpcString, $xmlrpcInt));

$findstate_doc = 'When passed an integer between 1 and 51 returns the
name of a US state, where the integer is the index of that state name
in an alphabetic order.';

$s = new xmlrpc_server( array(
    "examples.getStateName" => array(
        "function" => "findstate",
        "signature" => $findstate_sig,
        "docstring" => $findstate_doc
    )
));
```

Note that method signatures do not allow to check nested parameters, e.g. the number, names and types of the members of a struct param cannot be validated.

If a method that you want to expose has a definite number of parameters, but each of those parameters could reasonably be of multiple types, the array of acceptable signatures will easily grow into a combinatorial explosion. To avoid such a situation, the lib defines the global var `$xmlrpcValue`, which can be used in method signatures as a placeholder for 'any xmlrpc type':

```
$echoback_sig = array(array($xmlrpcValue, $xmlrpcValue));

$findstate_doc = 'Echoes back to the client the received value, regardless of its type';
```

```
$s = new xmlrpc_server( array(
    "echoBack" => array(
        "function" => "echoback",
        "signature" => $echoback_sig, // this sig guarantees that the method handler will be called with
        "docstring" => $echoback_doc
    )));
```

Methods `system.listMethods`, `system.methodHelp`, `system.methodSignature` and `system.multicall` are already defined by the server, and should not be reimplemented (see Reserved Methods below).

## Delaying the server response

You may want to construct the server, but for some reason not fulfill the request immediately (security verification, for instance). If you omit to pass to the constructor the dispatch map or pass it a second argument of 0 this will have the desired effect. You can then use the `service()` method of the server class to service the request. For example:

```
$s = new xmlrpc_server($myDispMap, 0); // second parameter = 0 prevents automatic servicing of request
// ... some code that does other stuff here
$s->service();
```

Note that the `service` method will print the complete result payload to screen and send appropriate HTTP headers back to the client, but also return the response object. This permits further manipulation of the response.

To prevent the server from sending HTTP headers back to the client, you can pass a second parameter with a value of `TRUE` to the `service` method. In this case, the response payload will be returned instead of the response object.

Xmlrpc requests retrieved by other means than HTTP POST bodies can also be processed. For example:

```
$s = new xmlrpc_server(); // not passing a dispatch map prevents automatic servicing of request
// ... some code that does other stuff here, including setting dispatch map into server object
$res = $s->service($xmlrpc_request_body, true); // parse a variable instead of POST body, retrieve response
// ... some code that does other stuff with xml response $res here
```

## Modifying the server behaviour

A couple of methods / class variables are available to modify the behaviour of the server. The only way to take advantage of their existence is by usage of a delayed server response (see above)

### setDebug()

This function controls whether the server is going to echo debugging messages back to the client as comments in response body. Valid values: 0,1,2,3, with 1 being the default. At level 0, no debug info is returned to the client. At level 2, the complete client request is added to the response, as part of the xml comments. At level 3, a new PHP error handler is set when executing user functions exposed as server methods, and all non-fatal errors are trapped and added as comments into the response.

### allow\_system\_funcs

Default\_value: `TRUE`. When set to `FALSE`, disables support for `System.xxx` functions in the server. It might be useful e.g. if you do not wish the server to respond to requests to `System.ListMethods`.

## compress\_response

When set to TRUE, enables the server to take advantage of HTTP compression, otherwise disables it. Responses will be transparently compressed, but only when an xmlrpc-client declares its support for compression in the HTTP headers of the request.

Note that the ZLIB php extension must be installed for this to work. If it is, `compress_response` will default to TRUE.

## response\_charset\_encoding

Charset encoding to be used for response (only affects string values).

If it can, the server will convert the generated response from `internal_encoding` to the intended one.

Valid values are: a supported xml encoding (only UTF-8 and ISO-8859-1 at present, unless mbstring is enabled), null (leave charset unspecified in response and convert output stream to US\_ASCII), 'default' (use xmlrpc library default as specified in `xmlrpc.inc`, convert output stream if needed), or 'auto' (use client-specified charset encoding or same as request if request headers do not specify it (unless request is US-ASCII: then use library default anyway)).

## Fault reporting

Fault codes for your servers should start at the value indicated by the global `$xmlrpcerruser + 1`.

Standard errors returned by the server include:

1 Unknown method	Returned if the server was asked to dispatch a method it didn't know about
2 Invalid return payload	This error is actually generated by the client, not server, code, but signifies that a server returned something it couldn't understand. A more detailed error report is sometimes added onto the end of the phrase above.
3 Incorrect parameters	This error is generated when the server has signature(s) defined for a method, and the parameters passed by the client do not match any of signatures.
4 Can't introspect: method unknown	This error is generated by the builtin <code>system.*</code> methods when any kind of introspection is attempted on a method undefined by the server.
5 Didn't receive 200 OK from remote server	This error is generated by the client when a remote server doesn't return HTTP/1.1 200 OK in response to a request. A more detailed error report is added onto the end of the phrase above.
6 No data received from server	This error is generated by the client when a remote server returns HTTP/1.1 200 OK in response to a request, but no response body follows the HTTP headers.
7 No SSL support compiled in	This error is generated by the client when trying to send a request with HTTPS and the CURL extension is not available to PHP.
8 CURL error	This error is generated by the client when trying to send a request with HTTPS and the HTTPS communication fails.
9-14 multical errors	These errors are generated by the server when something fails inside a <code>system.multicall</code> request.

100- XML parse errors

Returns 100 plus the XML parser error code for the fault that occurred. The `faultString` returned explains where the parse error was in the incoming XML stream.

## 'New style' servers

In the same spirit of simplification that inspired the `xmlrpc_client::return_type` class variable, a new class variable has been added to the server class: `functions_parameters_type`. When set to 'phpvals', the functions registered in the server dispatch map will be called with plain php values as parameters, instead of a single `xmlrpcmsg` instance parameter. The return value of those functions is expected to be a plain php value, too. An example is worth a thousand words:

```
function foo($usr_id, $out_lang='en') {
    global $xmlrpcerruser;

    ...

    if ($someErrorCondition)
        return new xmlrpcresp(0, $xmlrpcerruser+1, 'DOH!');
    else
        return array(
            'name' => 'Joe',
            'age' => 27,
            'picture' => new xmlrpcval(file_get_contents($picOfTheGuy), 'base64')
        );
}

$s = new xmlrpc_server(
    array(
        "examples.myFunc" => array(
            "function" => "bar::foobar",
            "signature" => array(
                array($xmlrpcString, $xmlrpcInt),
                array($xmlrpcString, $xmlrpcInt, $xmlrpcString)
            )
        )
    ), false);
$s->functions_parameters_type = 'phpvals';
$s->service();
```

There are a few things to keep in mind when using this simplified syntax:

to return an `xmlrpc` error, the method handler function must return an instance of `xmlrpcresp`. There is no other way for the server to know when an error response should be served to the client;

to return a base64 value, the method handler function must encode it on its own, creating an instance of an `xmlrpcval` object;

the method handler function cannot determine the name of the `xmlrpc` method it is serving, unlike standard handler functions that can retrieve it from the message object;

when receiving nested parameters, the method handler function has no way to distinguish a php string that was sent as base64 value from one that was sent as a string value;

this has a direct consequence on the support of `system.multicall`: a method whose signature contains `datetime` or `base64` values will not be available to `multicall` calls;

last but not least, the direct parsing of xml to php values is much faster than using `xmlrpcvals`, and allows the library to handle much bigger messages without allocating all available server memory or smashing PHP recursive call stack.

---

# Chapter 8. Global variables

Many global variables are defined in the `xmlrpc.inc` file. Some of those are meant to be used as constants (and modifying their value might cause unpredictable behaviour), while some others can be modified in your php scripts to alter the behaviour of the xml-rpc client and server.

## "Constant" variables

### `$xmlrpcerruser`

```
$xmlrpcerruser = 800;
```

The minimum value for errors reported by user implemented XML-RPC servers. Error numbers lower than that are reserved for library usage.

### `$xmlrpcI4`, `$xmlrpcInt`, `$xmlrpcBoolean`, `$xmlrpcDouble`, `$xmlrpcString`, `$xmlrpcDateTime`, `$xmlrpcBase64`, `$xmlrpcArray`, `$xmlrpcStruct`, `$xmlrpcValue`, `$xmlrpcNull`

For convenience the strings representing the XML-RPC types have been encoded as global variables:

```
$xmlrpcI4="i4";  
$xmlrpcInt="int";  
$xmlrpcBoolean="boolean";  
$xmlrpcDouble="double";  
$xmlrpcString="string";  
$xmlrpcDateTime="dateTime.iso8601";  
$xmlrpcBase64="base64";  
$xmlrpcArray="array";  
$xmlrpcStruct="struct";  
$xmlrpcValue="undefined";  
$xmlrpcNull="null";
```

### `$xmlrpcTypes`, `$xmlrpc_valid_parents`, `$xmlrpcerr`, `$xmlrpcstr`, `$xmlrpcerrxml`, `$xmlrpc_backslash`, `$_xh`, `$xml_iso88591_Entities`, `$xmlEntities`, `$xmlrpcs_capabilities`

Reserved for internal usage.

## Variables whose value can be modified

### `xmlrpc_defencoding`

```
$xmlrpc_defencoding = "UTF8";
```

This variable defines the character set encoding that will be used by the xml-rpc client and server to decode the received messages, when a specific charset declaration is not found (in the messages sent non-ascii chars are always encoded using character references, so that the produced xml is valid regardless of the charset encoding assumed).

Allowed values: "UTF8", "ISO-8859-1", "ASCII".

Note that the appropriate RFC actually mandates that XML received over HTTP without indication of charset encoding be treated as US-ASCII, but many servers and clients 'in the wild' violate the standard, and assume the default encoding is UTF-8.

## xmlrpc\_internalencoding

```
$xmlrpc_internalencoding = "ISO-8859-1";
```

This variable defines the character set encoding that the library uses to transparently encode into valid XML the xml-rpc values created by the user and to re-encode the received xml-rpc values when it passes them to the PHP application. It only affects xml-rpc values of string type. It is a separate value from `xmlrpc_defencoding`, allowing e.g. to send/receive xml messages encoded on-the-wire in US-ASCII and process them as UTF-8. It defaults to the character set used internally by PHP (unless you are running an MBString-enabled installation), so you should change it only in special situations, if e.g. the string values exchanged in the xml-rpc messages are directly inserted into / fetched from a database configured to return UTF8 encoded strings to PHP. Example usage:

```
<?php
include('xmlrpc.inc');
$xmlrpc_internalencoding = 'UTF-8'; // this has to be set after the inclusion above
$v = new xmlrpcval('î°â¼'î#î¼îµ'); // This xmlrpc value will be correctly serialized as the greek w
```

## xmlrpcName

```
$xmlrpcName = "XML-RPC for PHP";
```

The string representation of the name of the XML-RPC for PHP library. It is used by the client for building the User-Agent HTTP header that is sent with every request to the server. You can change its value if you need to customize the User-Agent string.

## xmlrpcVersion

```
$xmlrpcVersion = "2.2";
```

The string representation of the version number of the XML-RPC for PHP library in use. It is used by the client for building the User-Agent HTTP header that is sent with every request to the server. You can change its value if you need to customize the User-Agent string.

## xmlrpc\_null\_extension

When set to TRUE, the lib will enable support for the <NIL/> xmlrpc value, as per the extension to the standard proposed here. This means that <NIL/> tags will be parsed as valid xmlrpc, and the corresponding `xmlrpcvals` will return "null" for `scalarType()`.

---

# Chapter 9. Helper functions

XML-RPC for PHP contains some helper functions which you can use to make processing of XML-RPC requests easier.

## Date functions

The XML-RPC specification has this to say on dates:

Don't assume a timezone. It should be specified by the server in its documentation what assumptions it makes about timezones.

Unfortunately, this means that date processing isn't straightforward. Although XML-RPC uses ISO 8601 format dates, it doesn't use the timezone specifier.

We strongly recommend that in every case where you pass dates in XML-RPC calls, you use UTC (GMT) as your timezone. Most computer languages include routines for handling GMT times natively, and you won't have to translate between timezones.

For more information about dates, see ISO 8601: The Right Format for Dates [<http://www.uic.edu/year2000/datefmt.html>], which has a handy link to a PDF of the ISO 8601 specification. Note that XML-RPC uses exactly one of the available representations: CCYYMMDDTHH:MM:SS.

### iso8601\_encode

```
string iso8601_encode ( string $time_t, int $utc = 0 )
```

Returns an ISO 8601 formatted date generated from the UNIX timestamp *\$time\_t*, as returned by the PHP function `time()`.

The argument *\$utc* can be omitted, in which case it defaults to 0. If it is set to 1, then the function corrects the time passed in for UTC. Example: if you're in the GMT-6:00 timezone and set *\$utc*, you will receive a date representation six hours ahead of your local time.

The included demo program `vardemo.php` includes a demonstration of this function.

### iso8601\_decode

```
int iso8601_decode ( string $isoString, int $utc = 0 )
```

Returns a UNIX timestamp from an ISO 8601 encoded time and date string passed in. If *\$utc* is 1 then *\$isoString* is assumed to be in the UTC timezone, and thus the result is also UTC; otherwise, the timezone is assumed to be your local timezone and you receive a local timestamp.

## Easy use with nested PHP values

Dan Libby was kind enough to contribute two helper functions that make it easier to translate to and from PHP values. This makes it easier to deal with complex structures. At the moment support is limited to int, double, string, array, datetime and struct datatypes; note also that all PHP arrays are encoded as structs, except arrays whose keys are integer numbers starting with 0 and incremented by 1.

These functions reside in `xmlrpc.inc`.

### php\_xmlrpc\_decode

```
mixed php_xmlrpc_decode ( xmlrpcval $xmlrpc_val, array $options )
```

```
array php_xmlrpc_decode ( xmlrpcmsg $xmlrpcmsg_val, string $options )
```

Returns a native PHP value corresponding to the values found in the `xmlrpcval` *\$xmlrpc\_val*, translated into PHP types. Base-64 and datetime values are automatically decoded to strings.

In the second form, returns an array containing the parameters of the given *xmlrpcmsg\_val*, decoded to php types.

The *options* parameter is optional. If specified, it must consist of an array of options to be enabled in the decoding process. At the moment the only valid option is `decode_php_objs`. When it is set, php objects that have been converted to xml-rpc structs using the `php_xmlrpc_encode` function and a corresponding encoding option will be converted back into object values instead of arrays (provided that the class definition is available at reconstruction time).

**WARNING:** please take extreme care before enabling the `decode_php_objs` option: when php objects are rebuilt from the received xml, their constructor function will be silently invoked. This means that you are allowing the remote end to trigger execution of uncontrolled PHP code on your server, opening the door to code injection exploits. Only enable this option when you have complete trust of the remote server/client.

Example:

```
// wrapper to expose an existing php function as xmlrpc method handler
function foo_wrapper($m)
{
    $params = php_xmlrpc_decode($m);
    $retval = call_user_func_array('foo', $params);
    return new xmlrpcresp(new xmlrpcval($retval)); // foo return value will be serialized as string
}

$s = new xmlrpc_server(array(
    "examples.myFunc1" => array(
        "function" => "foo_wrapper",
        "signatures" => ...
    ));
```

## php\_xmlrpc\_encode

`xmlrpcval` **php\_xmlrpc\_encode** ( mixed *\$phpval*, array *\$options* )

Returns an `xmlrpcval` object populated with the PHP values in *\$phpval*. Works recursively on arrays and objects, encoding numerically indexed php arrays into array-type `xmlrpcval` objects and non numerically indexed php arrays into struct-type `xmlrpcval` objects. Php objects are encoded into struct-type `xmlrpcvals`, excepted for php values that are already instances of the `xmlrpcval` class or descendants thereof, which will not be further encoded. Note that there's no support for encoding php values into base-64 values. Encoding of date-times is optionally carried on on php strings with the correct format.

The *options* parameter is optional. If specified, it must consist of an array of options to be enabled in the encoding process. At the moment the only valid options are `encode_php_objs` and `auto_dates`.

The first will enable the creation of 'particular' `xmlrpcval` objects out of php objects, that add a "php\_class" xml attribute to their serialized representation. This attribute allows the function `php_xmlrpc_decode` to rebuild the native php objects (provided that the same class definition exists on both sides of the communication)

Example:

```
// the easy way to build a complex xml-rpc struct, showing nested base64 value and datetime values
$val = php_xmlrpc_encode(array(
    'first struct_element: an int' => 666,
    'second: an array' => array('apple', 'orange', 'banana'),
    'third: a base64 element' => new xmlrpcval('hello world', 'base64'),
    'fourth: a datetime' => '20060107T01:53:00'
), array('auto_dates'));
```

## php\_xmlrpc\_decode\_xml

```
xmlrpcval | xmlrpcresp | xmlrpcmsg php_xmlrpc_decode_xml ( string  
$xml, array $options )
```

Decodes the xml representation of either an xmlrpc request, response or single value, returning the corresponding php-xmlrpc object, or FALSE in case of an error.

The *options* parameter is optional. If specified, it must consist of an array of options to be enabled in the decoding process. At the moment, no option is supported.

Example:

```
$text = '<value><array><data><value>Hello world</value></data></array></value>';  
$val = php_xmlrpc_decode_xml($text);  
if ($val) echo 'Found a value of type ' . $val->kindOf(); else echo 'Found invalid xml';
```

## Automatic conversion of php functions into xmlrpc methods (and vice versa)

For the extremely lazy coder, helper functions have been added that allow to convert a php function into an xmlrpc method, and a remotely exposed xmlrpc method into a local php function - or a set of methods into a php class. Note that these comes with many caveat.

### wrap\_xmlrpc\_method

```
string wrap_xmlrpc_method ( $client, $methodname, $extra_options )  
  
string wrap_xmlrpc_method ( $client, $methodname, $signature, $timeout,  
$protocol, $funcname )
```

Given an xmlrpc server and a method name, creates a php wrapper function that will call the remote method and return results using native php types for both params and results. The generated php function will return an xmlrpcresp object for failed xmlrpc calls.

The second syntax is deprecated, and is listed here only for backward compatibility.

The server must support the `system.methodSignature` xmlrpc method call for this function to work.

The *client* param must be a valid `xmlrpc_client` object, previously created with the address of the target xmlrpc server, and to which the preferred communication options have been set.

The optional parameters can be passed as array key,value pairs in the *extra\_options* param.

The *signature* optional param has the purpose of indicating which method signature to use, if the given server method has multiple signatures (defaults to 0).

The *timeout* and *protocol* optional params are the same as in the `xmlrpc_client::send()` method.

If set, the optional *new\_function\_name* parameter indicates which name should be used for the generated function. In case it is not set the function name will be auto-generated.

If the *return\_source* optional parameter is set, the function will return the php source code to build the wrapper function, instead of evaluating it (useful to save the code and use it later as stand-alone xmlrpc client).

If the *encode\_php\_objs* optional parameter is set, instances of php objects later passed as parameters to the newly created function will receive a 'special' treatment that allows the server to

rebuild them as php objects instead of simple arrays. Note that this entails using a "slightly augmented" version of the xmlrpc protocol (ie. using element attributes), which might not be understood by xmlrpc servers implemented using other libraries.

If the `decode_php_objs` optional parameter is set, instances of php objects that have been appropriately encoded by the server using a coordinate option will be deserialized as php objects instead of simple arrays (the same class definition should be present server side and client side).

*Note that this might pose a security risk*, since in order to rebuild the object instances their constructor method has to be invoked, and this means that the remote server can trigger execution of unforeseen php code on the client: not really a code injection, but almost. Please enable this option only when you trust the remote server.

In case of an error during generation of the wrapper function, `FALSE` is returned, otherwise the name (or source code) of the new function.

Known limitations: server must support `system.methodsignature` for the wanted xmlrpc method; for methods that expose multiple signatures, only one can be picked; for remote calls with nested xmlrpc params, the caller of the generated php function has to encode on its own the params passed to the php function if these are structs or arrays whose (sub)members include values of type `base64`.

Note: calling the generated php function 'might' be slow: a new xmlrpc client is created on every invocation and an xmlrpc-connection opened+closed. An extra 'debug' param is appended to the parameter list of the generated php function, useful for debugging purposes.

Example usage:

```
$c = new xmlrpc_client('http://phpxmlrpc.sourceforge.net/server.php');
$function = wrap_xmlrpc_method($client, 'examples.getStateName');

if (!$function)
    die('Cannot introspect remote method');
else {
    $stateno = 15;
    $statename = $function($a);
    if (is_a($statename, 'xmlrpcresp')) // call failed
    {
        echo 'Call failed: '.$statename->faultCode().' Calling again with debug on';
        $function($a, true);
    }
    else
        echo "OK, state nr. $stateno is $statename";
}
```

## wrap\_php\_function

```
array    wrap_php_function    (    string    $funcname,    string
$wrapper_function_name, array $extra_options )
```

Given a user-defined PHP function, create a PHP 'wrapper' function that can be exposed as xmlrpc method from an `xmlrpc_server` object and called from remote clients, and return the appropriate definition to be added to a server's dispatch map.

The optional `$wrapper_function_name` specifies the name that will be used for the auto-generated function.

Since php is a typeless language, to infer types of input and output parameters, it relies on parsing the javadoc-style comment block associated with the given function. Usage of xmlrpc native types (such as `datetime.dateTime.iso8601` and `base64`) in the docblock `@param` tag is also allowed, if you need the php function to receive/send data in that particular format (note that `base64` encoding/decoding is transparently carried out by the lib, while `datetime` vals are passed around as strings).

Known limitations: requires PHP 5.0.3 +; only works for user-defined functions, not for PHP internal functions (reflection does not support retrieving number/type of params for those); the wrapped php function will not be able to programmatically return an xmlrpc error response.

If the `return_source` optional parameter is set, the function will return the php source code to build the wrapper function, instead of evaluating it (useful to save the code and use it later in a stand-alone xmlrpc server). It will be in the stored in the `source` member of the returned array.

If the `suppress_warnings` optional parameter is set, any runtime warning generated while processing the user-defined php function will be caught and not be printed in the generated xml response.

If the `extra_options` array contains the `encode_php_objs` value, wrapped functions returning php objects will generate "special" xmlrpc responses: when the xmlrpc decoding of those responses is carried out by this same lib, using the appropriate param in `php_xmlrpc_decode()`, the objects will be rebuilt.

In short: php objects can be serialized, too (except for their resource members), using this function. Other libs might choke on the very same xml that will be generated in this case (i.e. it has a nonstandard attribute on struct element tags)

If the `decode_php_objs` optional parameter is set, instances of php objects that have been appropriately encoded by the client using a coordinate option will be deserialized and passed to the user function as php objects instead of simple arrays (the same class definition should be present server side and client side).

*Note that this might pose a security risk*, since in order to rebuild the object instances their constructor method has to be invoked, and this means that the remote client can trigger execution of unforeseen php code on the server: not really a code injection, but almost. Please enable this option only when you trust the remote clients.

Example usage:

```
/**
 * State name from state number decoder. NB: do NOT remove this comment block.
 * @param integer $statego the state number
 * @return string the name of the state (or error description)
 */
function findstate($statego)
{
    global $stateNames;
    if (isset($stateNames[$statego-1]))
    {
        return $stateNames[$statego-1];
    }
    else
    {
        return "I don't have a state for the index '" . $statego . "'";
    }
}

// wrap php function, build xmlrpc server
$methods = array();
$findstate_sig = wrap_php_function('findstate');
if ($findstate_sig)
{
    $methods['examples.getStateName'] = $findstate_sig;
}
$srv = new xmlrpc_server($methods);
```

## Functions removed from the library

The following two functions have been deprecated in version 1.1 of the library, and removed in version 2, in order to avoid conflicts with the EPI xml-rpc library, which also defines two functions with the same names.

To ease the transition to the new naming scheme and avoid breaking existing implementations, the following scheme has been adopted:

- If EPI-XMLRPC is not active in the current PHP installation, the constant `XMLRPC_EPI_ENABLED` will be set to `'0'`
- If EPI-XMLRPC is active in the current PHP installation, the constant `XMLRPC_EPI_ENABLED` will be set to `'1'`

The following documentation is kept for historical reference:

## **xmlrpc\_decode**

```
mixed xmlrpc_decode ( xmlrpcval $xmlrpc_val )
```

Alias for `php_xmlrpc_decode`.

## **xmlrpc\_encode**

```
xmlrpcval xmlrpc_encode ( mixed $phpval )
```

Alias for `php_xmlrpc_encode`.

# **Debugging aids**

## **xmlrpc\_debugmsg**

```
void xmlrpc_debugmsg ( string $debugstring )
```

Sends the contents of *\$debugstring* in XML comments in the server return payload. If a PHP client has debugging turned on, the user will be able to see server debug information.

Use this function in your methods so you can pass back diagnostic information. It is only available from `xmlrpcs.inc`.

---

# Chapter 10. Reserved methods

In order to extend the functionality offered by XML-RPC servers without impacting on the protocol, reserved methods are supported in this release.

All methods starting with `system.` are considered reserved by the server. PHP for XML-RPC itself provides four special methods, detailed in this chapter.

Note that all server objects will automatically respond to clients querying these methods, unless the property `allow_system_funcs` has been set to `false` before calling the `service()` method. This might pose a security risk if the server is exposed to public access, e.g. on the internet.

## `system.getCapabilities`

## `system.listMethods`

This method may be used to enumerate the methods implemented by the XML-RPC server.

The `system.listMethods` method requires no parameters. It returns an array of strings, each of which is the name of a method implemented by the server.

## `system.methodSignature`

This method takes one parameter, the name of a method implemented by the XML-RPC server.

It returns an array of possible signatures for this method. A signature is an array of types. The first of these types is the return type of the method, the rest are parameters.

Multiple signatures (i.e. overloading) are permitted: this is the reason that an array of signatures are returned by this method.

Signatures themselves are restricted to the top level parameters expected by a method. For instance if a method expects one array of structs as a parameter, and it returns a string, its signature is simply "string, array". If it expects three integers, its signature is "string, int, int, int".

For parameters that can be of more than one type, the "undefined" string is supported.

If no signature is defined for the method, a not-array value is returned. Therefore this is the way to test for a non-signature, if `$resp` below is the response object from a method call to `system.methodSignature`:

```
$v = $resp->value();
if ($v->kindOf() != "array") {
    // then the method did not have a signature defined
}
```

See the `introspect.php` demo included in this distribution for an example of using this method.

## `system.methodHelp`

This method takes one parameter, the name of a method implemented by the XML-RPC server.

It returns a documentation string describing the use of that method. If no such string is available, an empty string is returned.

The documentation string may contain HTML markup.

## **system.multicall**

This method takes one parameter, an array of 'request' struct types. Each request struct must contain a *methodName* member of type string and a *params* member of type array, and corresponds to the invocation of the corresponding method.

It returns a response of type array, with each value of the array being either an error struct (containing the *faultCode* and *faultString* members) or the successful response value of the corresponding single method call.

---

# Chapter 11. Examples

The best examples are to be found in the sample files included with the distribution. Some are included here.

## XML-RPC client: state name query

Code to get the corresponding state name from a number (1-50) from the demo server available on SourceForge

```
$m = new xmlrpcmsg('examples.getStateName',  
    array(new xmlrpcval($HTTP_POST_VARS["stateno"], "int")));  
$c = new xmlrpc_client("/server.php", "phpxmlrpc.sourceforge.net", 80);  
$r = $c->send($m);  
if (!$r->faultCode()) {  
    $v = $r->value();  
    print "State number " . htmlentities($HTTP_POST_VARS["stateno"]) . " is " .  
        htmlentities($v->scalarval()) . "<BR>";  
    print "<HR>I got this value back<BR><PRE>" .  
        htmlentities($r->serialize()) . "</PRE><HR>\n";  
} else {  
    print "Fault <BR>";  
    print "Code: " . htmlentities($r->faultCode()) . "<BR>" .  
        "Reason: '" . htmlentities($r->faultString()) . "'<BR>";  
}
```

## Executing a multical call

To be documented...

---

# Chapter 12. Frequently Asked Questions

## How to send custom XML as payload of a method call

Unfortunately, at the time the XML-RPC spec was designed, support for namespaces in XML was not as ubiquitous as it is now. As a consequence, no support was provided in the protocol for embedding XML elements from other namespaces into an xmlrpc request.

To send an XML "chunk" as payload of a method call or response, two options are available: either send the complete XML block as a string xmlrpc value, or as a base64 value. Since the '<' character in string values is encoded as '&lt;' in the xml payload of the method call, the XML string will not break the surrounding xmlrpc, unless characters outside of the assumed character set are used. The second method has the added benefits of working independently of the charset encoding used for the xml to be transmitted, and preserving exactly whitespace, whilst incurring in some extra message length and cpu load (for carrying out the base64 encoding/decoding).

## Is there any limitation on the size of the requests / responses that can be successfully sent?

Yes. But I have no hard figure to give; it most likely will depend on the version of PHP in usage and its configuration.

Keep in mind that this library is not optimized for speed nor for memory usage. Better alternatives exist when there are strict requirements on throughput or resource usage, such as the php native xmlrpc extension (see the PHP manual for more information).

Keep in mind also that HTTP is probably not the best choice in such a situation, and XML is a deadly enemy. CSV formatted data over socket would be much more efficient.

If you really need to move a massive amount of data around, and you are crazy enough to do it using phpxmlrpc, your best bet is to bypass usage of the xmlrpcval objects, at least in the decoding phase, and have the server (or client) object return to the calling function directly php values (see `xmlrpc_client::return_type` and `xmlrpc_server::functions_parameters_type` for more details).

## My server (client) returns an error whenever the client (server) returns accented characters

To be documented...

## My php error log is getting full of "deprecated" errors on different lines of xmlrpc.inc and xmlrpcs.inc

This happens when the PHP in usage is version 5, and the error reporting level is set to include E\_STRICT errors. Since the main development platform of the library remains (for the time being) PHP 4, there are no plans to fix this asap. The best workaround is to set the error reporting level to E\_ALL ^ E\_STRICT.

## How to enable long-lasting method calls

To be documented...

## My client returns "XML-RPC Fault #2: Invalid return payload: enable debugging to examine incoming payload": what should I do?

The response you are seeing is a default error response that the client object returns to the php application when the server did not respond to the call with a valid xmlrpc response.

The most likely cause is that you are not using the correct URL when creating the client object, or you do not have appropriate access rights to the web page you are requesting, or some other common http misconfiguration.

To find out what the server is really returning to your client, you have to enable the debug mode of the client, using `$client->setdebug(1);`

## How can I save to a file the xml of the xmlrpc responses received from servers?

If what you need is to save the responses received from the server as xml, you have two options:

1- use the `serialize()` method on the response object.

```
$resp = $client->send($msg);
if (!$resp->faultCode())
    $data_to_be_saved = $resp->serialize();
```

Note that this will not be 100% accurate, since the xml generated by the response object can be different from the xml received, especially if there is some character set conversion involved, or such (eg. if you receive an empty string tag as `<string/>`, `serialize()` will output `<string></string>`), or if the server sent back as response something invalid (in which case the xml generated client side using `serialize()` will correspond to the error response generated internally by the lib).

2 - set the client object to return the raw xml received instead of the decoded objects:

```
$client = new xmlrpc_client($url);
$client->return_type = 'xml';
$resp = $client->send($msg);
if (!$resp->faultCode())
    $data_to_be_saved = $resp->value();
```

Note that using this method the xml response response will not be parsed at all by the library, only the http communication protocol will be checked. This means that xmlrpc responses sent by the server that would have generated an error response on the client (eg. malformed xml, responses that have faultcode set, etc...) now will not be flagged as invalid, and you might end up saving not valid xml but random junk...

## Can I use the ms windows character set?

If the data your application is using comes from a Microsoft application, there are some chances that the character set used to encode it is CP1252 (the same might apply to data received from an external xmlrpc server/client, but it is quite rare to find xmlrpc toolkits that encode to CP1252 instead of UTF8). It is a character set which is "almost" compatible with ISO 8859-1, but for a few extra characters.

PHP-XMLRPC only supports the ISO 8859-1 and UTF8 character sets. The net result of this situation is that those extra characters will not be properly encoded, and will be received at the other end of the XML-RPC transmission as "garbled data". Unfortunately the library cannot provide real support for CP1252 because of limitations in the PHP 4 xml parser. Luckily, we tried our best to support this character set anyway, and, since version 2.2.1, there is some form of support, left commented in the code.

To properly encode outgoing data that is natively in CP1252, you will have to uncomment all relative code in the file xmlrpc.inc (you can search for the string "1252"), then set `$GLOBALS['xmlrpc_internalencoding'] = 'CP1252'` ; Please note that all incoming data will then be fed to your application as UTF-8 to avoid any potential data loss.

## Does the library support using cookies / http sessions?

In short: yes, but a little coding is needed to make it happen.

The code below uses sessions to e.g. let the client store a value on the server and retrieve it later.

```
$resp = $client->send(new xmlrpcmsg('registervalue', array(new xmlrpcval('foo'), new xmlrpcval('bar'))));
if (!$resp->faultCode())
{
    $cookies = $resp->cookies();
    if (array_key_exists('PHPSESSID', $cookies)) // nb: make sure to use the correct session cookie name
    {
        $session_id = $cookies['PHPSESSID']['value'];

        // do some other stuff here...

        $client->setcookie('PHPSESSID', $session_id);
        $val = $client->send(new xmlrpcmsg('getvalue', array(new xmlrpcval('foo'))));
    }
}
```

Server-side sessions are handled normally like in any other php application. Please see the php manual for more information about sessions.

NB: unlike web browsers, not all xmlrpc clients support usage of http cookies. If you have troubles with sessions and control only the server side of the communication, please check with the makers of the xmlrpc client in use.

---

# Appendix A. Integration with the PHP xmlrpc extension

To be documented more...

In short: for the fastest execution possible, you can enable the php native xmlrpc extension, and use it in conjunction with phpxmlrpc. The following code snippet gives an example of such integration

```
/** client side */
$c = new xmlrpc_client('http://phpxmlrpc.sourceforge.net/server.php');

// tell the client to return raw xml as response value
$c->return_type = 'xml';

// let the native xmlrpc extension take care of encoding request parameters
$r = $c->send(xmlrpc_encode_request('examples.getStateName', $_POST['stateno']));

if ($r->faultCode())
    // HTTP transport error
    echo 'Got error ' . $r->faultCode();
else
{
    // HTTP request OK, but XML returned from server not parsed yet
    $v = xmlrpc_decode($r->value());
    // check if we got a valid xmlrpc response from server
    if ($v === NULL)
        echo 'Got invalid response';
    else
        // check if server sent a fault response
        if (xmlrpc_is_fault($v))
            echo 'Got xmlrpc fault ' . $v['faultCode'];
        else
            echo 'Got response: ' . htmlentities($v);
}
```

---

## Appendix B. Substitution of the PHP xmlrpc extension

Yet another interesting situation is when you are using a ready-made php application, that provides support for the XMLRPC protocol via the native php xmlrpc extension, but the extension is not available on your php install (e.g. because of shared hosting constraints).

Since version 2.1, the PHP-XMLRPC library provides a compatibility layer that aims to be 100% compliant with the xmlrpc extension API. This means that any code written to run on the extension should obtain the exact same results, albeit using more resources and a longer processing time, using the PHP-XMLRPC library and the extension compatibility module. The module is part of the EXTRAS package, available as a separate download from the [sourceforge.net](https://sourceforge.net) website, since version 0.2

---

# Appendix C. 'Enough of xmlrpcvals!': new style library usage

To be documented...

In the meantime, see docs about `xmlrpc_client::return_type` and `xmlrpc_server::functions_parameters_types`, as well as `php_xmlrpc_encode`, `php_xmlrpc_decode` and `php_xmlrpc_decode_xml`

---

# Appendix D. Usage of the debugger

A webservice debugger is included in the library to help during development and testing.

The interface should be self-explicative enough to need little documentation.

The most useful feature of the debugger is without doubt the "Show debug info" option. It allows to have a screen dump of the complete http communication between client and server, including the http headers as well as the request and response payloads, and is invaluable when troubleshooting problems with charset encoding, authentication or http compression.

The debugger can take advantage of the JSONRPC library extension, to allow debugging of JSON-RPC webservices, and of the JS-XMLRPC library visual editor to allow easy mouse-driven construction of the payload for remote methods. Both components have to be downloaded separately from the [sourceforge.net](http://sourceforge.net) web pages and copied to the debugger directory to enable the extra functionality:

- to enable jsonrpc functionality, download the PHP-XMLRPC EXTRAS package, and copy the file `jsonrpc.inc` either to the same directory as the debugger or somewhere in your php include path
- to enable the visual value editing dialog, download the JS-XMLRPC library, and copy somewhere in the web root files `visualeditor.php`, `visualeditor.css` and the folders `yui` and `img`. Then edit the debugger file `controller.php` and set appropriately the variable `$editorpath`.
